Filed:	Herewith	Dated:	February 19, 2002
For:	METHOD AND APPARATUS FOR MANUFACTURING PRODUCTS AND PLACING LABELS IN A MOLD		

Commissioner for Patents  
Washington, DC 20231

**PRELIMINARY AMENDMENT**

Sir:

In order to place the present application in condition for examination on the merits  
Applicant submits the following amendment for entry in the above-identified application.

**IN THE CLAIMS:**

Please amend Claims 3, 5-7, 9, 10, 13, 14, 16-18, 23-25, 30, 32-38, 41, 42, and 44 to  
read as follows:

3. (Amended) A method according to claim 1, wherein the enclosed, label-forming part is taken hold of using vacuum means provided in, at least on, the retaining element.

Applicant: Hoogland, Hendrik Antonius  
Serial No: Unassigned  
Our Docket: 294-121 PCT/US  
Page 2

5. (Amended) A method according to claim 1, wherein the label-forming part is taken hold of using static charge of the retaining element and/or the label forming part.

6. (Amended) A method according to claim 1, wherein the label-forming part is taken hold of using adhesion between the label-forming part and the retaining element.

7. (Amended) A method according to claim 1, wherein the label-forming part is taken hold of prior to its being cut loose.

9. (Amended) A method according to claim 7, wherein the label-forming part, prior to being cut loose, is taken hold of by the retaining element.

10. (Amended) A method according to claim 1, wherein the label is transferred from the retaining element to an insertion device for placement of the label in a mold, with the label being taken over by the insertion device in approximately the same position.

13. (Amended) A method according to claim 11, wherein on the carrier a first blanking plate surrounding or forming the blanking opening is secured, while on the blanking punch a complementary second blanking plate is secured.

14. (Amended) A method according to claim 1, wherein the film web is printed, prior to the formation of the labels.

Applicant: Hoogland, Hendrik Antonius  
 Serial No: Unassigned  
 Our Docket: 294-121 PCT/US  
 Page 3

16. (Amended) A method according to claim 1, wherein the label, at the least the label-forming part, is slightly stretched, at least on the retaining element, preferably during or immediately prior to the label-forming part being taken hold of by the retaining element.

17. (Amended) A method for placing a label in a mold for in-mold labeling injection molded products, wherein the or each label to be placed is manufactured with a method according to claim 1, and subsequently is arranged in the mold against at least one wall portion and is secured against it, preferably through reduced pressure, adhesion or static charge.

18. (Amended) A method according to claim 1, wherein labels are manufactured from a film web having a thickness of less than 30 micrometers, more particularly less than 20 micrometers, and preferably less than 15 micrometers.

23. (Amended) A method according to claim 21, wherein using the removal device at least one insert is placed in, at least on the closing part of the mold, preferably approximately simultaneously with the engagement of the product.

24. (Amended) A method according to claim 20, wherein the or each product in the respective cavity is engaged with the engaging means in openings, at least cavities in a longitudinal wall of the product, the or each said movable bounding part further comprising

Applicant: Hoogland, Hendrik Antonius  
Serial No: Unassigned  
Our Docket: 294-121 PCT/US  
Page 4

means which engage on the side of the product located rearwards in the ejection direction, for obtaining an improved pressure distribution.

25. (Amended) A method according to claim 20, wherein the product is injection molded with at least one hinge, while on opposite sides of the at least one hinge at least one and preferably at least two engaging means are provided.

30. (Amended) An apparatus according to claim 26, wherein the blanking opening is formed, at least surrounded, by a first blanking plate, while the blanking punch is provided with a second, complementary blanking plate, the blanking plates being exchangeable with other first and/or blanking plates.

32. (Amended) An apparatus according to claim 26, wherein the carrier is arranged for taking up substantially the complete blanking forces.

33. (Amended) An apparatus according to claim 26, wherein the pickup means comprise vacuum means at least adjacent a circumferential edge of a surface of the retaining means which during use is moved against the film web, preferably distributed over substantially the entire said surface.

34. (Amended) An apparatus according to claim 26, wherein the retaining means comprise a surface which is held against the label during use, and the label is slightly

Applicant: Hoogland, Hendrik Antonius  
Serial No: Unassigned  
Our Docket: 294-121 PCT/US  
Page 5

stretched over said surface during use, while the cutting means are arranged for cutting loose the label along the outer contour of said surface.

35. (Amended) An apparatus according to claim 26, wherein the cutting means comprise a blanking punch or cutting tool.

36. (Amended) An apparatus according to claim 26, wherein the retaining means are arranged for directly placing the or each label in a mold.

37. (Amended) An apparatus according to claim 26, wherein an insertion device is provided, arranged for taking over from the retaining means a label picked up therewith, such that it can be transferred with the aid of the insertion device into an opened mold.

38. (Amended) An apparatus according to claim 26, wherein at least the insertion device is provided with a surface for taking over the label, which surface is of a smooth finish, while holding means are provided for taking hold of and holding the label in a slightly stretched condition, which holding means are so designed that they fix the label at some distance from said surface, while in a condition wherein no label is being held they are disposed substantially flush with said surface

42. (Amended) A mold according to claim 39, wherein the or each respective bounding part is mounted in guide means which upon movement in the ejection direction take care of the release of the product from the engaging parts near the end of the movement.

44. (Amended) An injection molded product, in particular according to claim 43, wherein the product is at least largely transparent and has been demolded from a mold according to claim 39.

In order to place the present application in condition for examination in the U.S. Patent Office, Applicant has amended the Claims to conform to U.S. practice. No new subject matter has been introduced as a result of this Amendment. As a result of the present Amendment, Claims 1-44 remain in the application for purpose of prosecution.

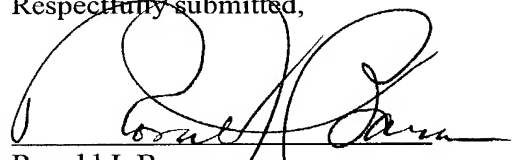

As a result of this Amendment no additional fees should be assessed as a result of filing multiple dependent claims. Therefore, since new matter has not been introduced as a result of this Amendment, entry hereof and examination and favorable consideration are

**VERSION OF AMENDMENT WITH MARKS**  
**TO SHOW CHANGES MADE**

**IN THE CLAIMS:**

Please amend Claims 3, 5-7, 9, 10, 13, 14, 16-18, 23-25, 30, 32-38, 41, 42 and 44, to read as follows:

3. (Amended) A method according to claim 1 [or 2], wherein the enclosed, label-forming part is taken hold of using vacuum means provided in, at least on, the retaining element.

5. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the label-forming part is taken hold of using static charge of the retaining element and/or the label forming part.

6. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the label-forming part is taken hold of using adhesion between the label-forming part and the retaining element.

7. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the label-forming part is taken hold of prior to its being cut loose.

Applicant: Hoogland, Hendrik Antonius  
Serial No: Unassigned  
Our Docket: 294-121 PCT/US  
Page 9

9. (Amended) A method according to claim 7 [or 8], wherein the label-forming part, prior to being cut loose, is taken hold of by the retaining element.

10. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the label is transferred from the retaining element to an insertion device for placement of the label in a mold, with the label being taken over by the insertion device in approximately the same position.

13. (Amended) A method according to claim 11 [or 12], wherein on the carrier a first blanking plate surrounding or forming the blanking opening is secured, while on the blanking punch a complementary second blanking plate is secured.

14. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the film web is printed, prior to the formation of the labels.

16. (Amended) A method according to claim 1 [any one of the preceding claims], wherein the label, at the least the label-forming part, is slightly stretched, at least on the retaining element, preferably during or immediately prior to the label-forming part being taken hold of by the retaining element.

17. (Amended) A method for placing a label in a mold for in-mold labeling injection molded products, wherein the or each label to be placed is manufactured with a method according to claim 1 [any one of the preceding claims], and subsequently is arranged

Applicant: Hoogland, Hendrik Antonius  
Serial No: Unassigned

in the mold against at least one wall portion and is secured against it, preferably through reduced pressure, adhesion or static charge.

18. (Amended) A method according to claim 1 [any one of the preceding claims], wherein labels are manufactured from a film web having a thickness of less than 30 micrometers, more particularly less than 20 micrometers, and preferably less than 15 micrometers.

23. (Amended) A method according to claim 21 [any one of claims 21 or 22], wherein using the removal device at least one insert is placed in, at least on the closing part of the mold, preferably approximately simultaneously with the engagement of the product.

24. (Amended) A method according to claim 20 [any one of claims 20-23], wherein the or each product in the respective cavity is engaged with the engaging means in openings, at least cavities in a longitudinal wall of the product, the or each said movable bounding part further comprising means which engage on the side of the product located rearwards in the ejection direction, for obtaining an improved pressure distribution.

25. (Amended) A method according to claim 20 [any one of claims 20-24], wherein the product is injection molded with at least one hinge, while on opposite sides of the at least one hinge at least one and preferably at least two engaging means are provided.

Applicant: Hoogland, Hendrik Antonius  
Serial No. Unassigned  
Our Docket: 294-121 PCT/US  
Page 11

30. (Amended) An apparatus according to claim 26 [any one of claims 26-29], wherein the blanking opening is formed, at least surrounded, by a first blanking plate, while the blanking punch is provided with a second, complementary blanking plate, the blanking plates being exchangeable with other first and/or blanking plates.

32. (Amended) An apparatus according to claim 26 [any one of claims 26-31], wherein the carrier is arranged for taking up substantially the complete blanking forces.

33. (Amended) An apparatus according to claim 26 [any one of claims 26-32], wherein the pickup means comprise vacuum means at least adjacent a circumferential edge of a surface of the retaining means which during use is moved against the film web, preferably distributed over substantially the entire said surface.

34. (Amended) An apparatus according to claim 26 [any one of claims 26 or 33], wherein the retaining means comprise a surface which is held against the label during use, and the label is slightly stretched over said surface during use, while the cutting means are arranged for cutting loose the label along the outer contour of said surface.

35. (Amended) An apparatus according to claim 26 [any one of claims 26-34], wherein the cutting means comprise a blanking punch or cutting tool.

36. (Amended) An apparatus according to claim 26 [any one of claims 26-35], wherein the retaining means are arranged for directly placing the or each label in a mold.

Applicant: Hoogland, Hendrik Antonius  
 Serial No: Unassigned  
 Our Docket: 294-121 PCT/US  
 Page 12

37. (Amended) An apparatus according to claim 26 [any one of claims 26-36], wherein an insertion device is provided, arranged for taking over from the retaining means a label picked up therewith, such that tit can be transferred with the aid of the insertion device into an opened mold.

38. (Amended) An apparatus according to claim 26 [any one of claims 26-38], wherein at least the insertion device is provided with a surface for taking over the label, which surface is of a smooth finish, while holding means are provided for taking hold of and holding the label in a slightly stretched condition, which holding means are so designed that they fix the label at some distance from said surface, while in a condition wherein no label is being held they are disposed substantially flush with said surface

41. (Amended) A mold according to claim 39 [or 40], wherein the or each engaging part is arranged for engagement of or behind an undercut in the product.

42. (Amended) A mold according to claim 39 [any one of claims 39-41], wherein the or each respective bounding part is mounted in guide means which upon movement in the ejection direction take care of the release of the product from the engaging parts near the end of the movement.

44. (Amended) An injection molded product, in particular according to claim 43, wherein the product is at least largely transparent and has been demolded from a mold according to claim 39 [any one of claims 39-42].

PCT/NL.00/00581

Title: Method and apparatus for manufacturing products and placing labels in a mold.

This invention relates to a method for manufacturing labels for placement in a mold. Such a method is known from practice.

In this known method, labels are manufactured and loosely stacked onto each other, and by means of a transfer device the topmost label of a stack is picked up and transferred to a mold cavity, where the label is suitably placed. Thereafter, a plastic is sprayed against this label for forming a desired article. Such a method is usually designated by, for instance, in-mold labeling. This known method has as a disadvantage that the labels are to be loosely manufactured and stacked, which requires that the labels be taken off the stack without this involving wrinkling, tearing, folding or other damage of the labels. Moreover, the conditions under which the labels are stacked, picked up and transferred into the mold must be controlled particularly well to obtain proper placement.

It has previously been proposed that labels, prior to placement, be cut or punched from a web of film, these labels be subsequently picked up by a transfer device and be placed in the mold cavity in a suitable manner. Such a method provides the advantage that the labels can be supplied in a particularly simple manner, viz., for instance, from a roll, and can be cut *in situ*, immediately prior to placement. Such a method, however, entails a disadvantage in that the labels, upon being cut or blanked, come to lie at least partly free, so that undesired changes in position may occur. Moreover, this known method still involves the disadvantage that prior to and during pickup and transfer of the label, the label may sustain damage, for instance by folding, wrinkling and the like. Further, the label, after being cut out or blanked, is to be picked up from the web of film before it can be transferred, which is time-consuming.

A further disadvantage of this known method is that the labels must have a relatively high dimensional stiffness, since in this known method, the labels are engaged only at a portion of their surface, such that the circumferential edges are free.

GB A 2 292 109 discloses an apparatus for cutting a number of labels simultaneously from a strip of a foil material, which cut out labels are transferred by the punches to a pressure pad with which the labels are

30-11-2001

10059026 061300 NL0000581

ART 34 AMDT

new page 1a

transferred to a die. The labels are cut loose by the punches through a cutting die. During transfer of the labels these are carried loose on the punches.

5 The object of the present invention is to provide a method for manufacturing labels, which avoids the disadvantages of the method described, while maintaining the advantages thereof. To that end, a method

10

15

AMENDED SHEET

Empfangszeit 30-nov-10-22

according to the present invention is characterized by the features according to claim 1.

By making use of a retaining element with which a part of the film web can be enclosed against the supporting carrier, which enclosed part is subsequently cut loose from the film web, the advantage is achieved that deformations, creases and the like can be simply prevented, even if no ideally sharp cutting means are utilized. By taking hold of the so cut and formed label with the retaining element and by subsequently picking up the label from the carrier with the retaining element, the necessity of having to take over the label is avoided, and so the label is held in the desired position at all times. This means there is no risk of the label intermediately becoming disengaged, for instance from the carrier, to possibly deform still by creasing, folding or the like. Preferably, the retaining means at the same time form transport means for displacing the cut-loose labels and optionally introducing them into a mold.

Accordingly, a method according to the invention provides the advantage that in a particularly fast and simple manner, particularly accurately, labels can be manufactured for placement in a mold, regardless of the thickness of the film from which the labels are cut.

In a preferred embodiment, a method according to the present invention is characterized by the features according to claim 2.

The use of a retaining element having an outer contour substantially corresponding to that of the desired label provides the advantage that the label-forming part can be simply cut loose along the outer contour, so that particularly sharp cuts are obtained and damage of the label is prevented still better. Moreover, when the label is being picked up and transferred, the retaining element will still extend along the outer contour of the label and thereby protect it properly. This further simplifies particularly accurate placement of the label in a mold or transfer device.

The retaining element is preferably provided with vacuum means for holding the label, preferably such that the label is slightly stretched, at least pulled taut, on the retaining element, thereby simply preventing deformations of the label. Naturally, the label can be held in other ways as well, for instance through static charge, adhesion and the like, optionally in combination.

The retaining means, in particular pickup means thereof, such as vacuum cups or the like, are preferably held against the film strip, in particular the or each label-forming part thereof, prior to the blanking of the label. It is then preferred that the label is already engaged by the retaining means before being blanked. As a result, the label can be held

engaging parts which are either enclosed in the ejection direction between two product parts or enclose a product part in the ejection direction in a form-closing manner, such that the engaging parts retain the product. Only when the product has been moved over a pre-selected distance in the ejection direction, wholly or partly outside the respective cavity, are the engaging parts moved relative to each other and/or the cavity, such that the product can come off the engaging parts and can be carried off. To that end, use can be made of gravity, but it is preferred that the product be engaged by a removal device before the whole has come off the engaging parts.

10 In a further advantageous embodiment, a method according to the invention is characterized by the features according to claim 23.

In such a method, approximately simultaneously with the engagement of a product with the aid of the removal device, an insert, for instance a core part, a label or the like is placed on the opposite side on, at least at, a closing part of the mold, such that upon closure of the mold the respective insert is moved into the opposite cavity and defines at least a part of the cavity. During injection molding, the respective insert is preferably fixedly incorporated into the product, such that it is ejected along with the product. Such a method provides the advantage that inserts can be rapidly placed during removal of the products, so that shorter cycle times can be obtained.

By providing engagement means that engage in openings or the like in the product, the advantage is achieved that in a finished product it is camouflaged still better where the ejection means have engaged. Moreover, this makes it possible in a particularly simple manner to enclose the respective product in a form-closing manner and to move it in a controlled manner, while moreover the engagement means can form desired undercuts without this necessitating additional slides, moving core parts or the like. As a result, a mold for use in such a method is simplified still further.

30 When in such a method the or each movable bounding part is further provided with means that engage the side of the product located at the rear in the ejection direction, in a simple manner a still more advantageous pressure distribution can be obtained in that a relatively large surface is available. In particular, such a rearward part can engage, for instance, along a complete longitudinal wall of the respective product.

5

15

20

25

35

specimens, and the removed plates can be reground for reuse or can be discarded. Thus still less time is needed to keep the blanking means accurate, while the blanking means can moreover be simply adapted to a new form of label.

5 In further elaboration, an apparatus according to the present invention is characterized by the features according to claim 36.

The use of a blanking punch or cutting tool for cutting out the labels from the film provides the advantage that the labels can be cut loose in a single movement. As the label is locked between the carrier and the retaining means, the label is thus prevented in a simple manner from being  
10 damaged by the punch, for instance in that the punch has no optimum sharpness anymore.

In a further advantageous embodiment, an apparatus according to the invention is further characterized by the features according to claim 37.

15 Direct placement of the labels in the mold with the aid of the retaining means provides the advantage that faster placement is possible, without intermediate transfer, so that shorter cycle times are enabled. In particular also when the blanking forces are substantially taken up by the blanking punch and the blanking opening, at least the cutting part thereof, and hence substantially not by the retaining means. Indeed, as a  
20 consequence, the retaining means and the operating means for movement thereof can be made of relatively light design, so that the movement forces that act on them are reduced. Partly as a consequence of that, moreover, higher accelerations and decelerations are possible, so that the cycle times  
25 can be shortened still further.

The invention further relates to an injection mold characterized by the features according to claim 41.

By the use of at least one part at least partly bounding the respective cavity, that is, product-forming, which is movably arranged as ejector means, which movable part is provided with means with which the  
30 product formed in the cavity can be engaged, at least can be retained during an ejection movement, the advantage is achieved that the product, in a steered and controlled manner, can be moved out of the cavity and can be transferred to a removal device, or be released outside the respective cavity.  
35 As a result, at all times the position of the product can be accurately defined during ejection, while damage of the product can be simply prevented since

a shaping part of the mold transmits the ejection pressure. In particular when use is made of a removal device with which the products to be taken out are to be transferred in a pre-selected position to further processing devices, a mold according to the invention is particularly advantageous because during the ejection no undesired positional changes will occur. This means that products can rapidly and uniformly be made ready for further processing, in principle without this requiring a check. The engaging parts here engage at least substantially remote from the rear side of the product, viewed in the ejection direction.

In a mold according to the invention, the movably arranged parts at least partly bounding the cavity during injection molding can contain undercuts and/or define undercuts in the product, such that the cavity is not, at least poorly, clearing. Indeed, inasmuch as the respective bounding parts are used as ejector means, they can move along out of the cavity and then release the product, for instance by moving the respective bounding parts apart relative to each other in a direction substantially at right angles to the ejection direction, or by loosening the product from the respective bounding parts by movement in a direction which includes an angle with the ejection direction. In the latter embodiment, the product can, for instance, be moved away at right angles to the ejection direction. Thus, with a relatively simple mold, the possibility is afforded of injection molding non-withdrawable, at least poorly withdrawable, products, so that a particularly great freedom of design is obtained.

In the use of such a mold for the manufacture of products labeled in-mold in the manner described earlier, the additional advantage is achieved that the label, at least the imprint, is not damaged during ejection.

The invention further relates to a product manufactured by injection molding, characterized by the features according to claim 45.

Such a product provides the advantage that it has a pleasing appearance due to the label, while, for instance, product information, recognition means and the like have been formed integrally with the product, while further the properties of the labeled wall will substantially not be influenced by the label, since particularly thin labels have been used.

Further advantageous embodiments of a method and apparatus according to the invention are set forth in the dependent claims.

To clarify the invention, exemplary embodiments of an apparatus and method according to the invention will be further explained with reference to the drawings. In the drawings:

35 In this description, the same or corresponding parts have the same or corresponding reference numerals.

Fig. 1 shows a forming apparatus 1 for forming labels 2 from a film web 4. The forming apparatus 1 comprises carrier means 6, for instance a flat table over which a film web 4 can be supplied by supply means 8 from a roll of film 10. On the opposite side of the carrier means 6, the film web, at least the remainder thereof, can be discharged by film discharge means 12 suitable for the purpose. On the side of the film web 4 remote from the carrier means 6, retaining means 14 are placed, which are movably arranged, as will be described hereinafter in more detail. In Fig. 5 the retaining means 14 are shown in perspective view, from the closing side 16 which is proximal to the film web 4 during use. In the retaining means 14, pickup means 18 are provided, designed as vacuum means in the embodiment shown. These pickup means 18 comprise a number of vacuum cups 20 which are open on the side proximal to the pressure surface 16 and which are connected through a vacuum line 22 to a vacuum pump 24, schematically represented in Fig. 1. On the pressure surface 16, the outer contour 26 of a label 2 to be formed is indicated. The vacuum cups 20 are arranged at least along the inside edge of this outer contour 26, in a substantially continuous series. For that matter, vacuum cups 20 may also be provided on the rest of the surface within the outer contour 26, as is indicated in Fig. 5 by broken lines. It will be clear, for that matter, that other kinds of vacuum means can be provided, for instance in the form of a perforated plate, an air-permeable membrane or the like. The outer contour 26 can be of planar extension in the pressure surface 16, but may also be designed in the form of a groove or bulge.

In the carrier means 6, cutting means 28 are included, which are movable by operating means 30, in particular cylinder/piston assemblies 32. By means of a pump 34, a pressure medium can be introduced into the piston/cylinder assemblies 32, enabling the cutting means 28 to be so moved as to have their cutting edge 36 extending above the surface of the carrier means 6. The cutting means 28 preferably have a shape identical to the outer contour 26 of the label 2.

A forming apparatus 1 according to the invention can be used as follows.

A film web 4 having preferably a small thickness, for instance less than 30 micrometers, is passed level over the surface of the carrier means 6, with the cutting means 28 retracted below said surface. Thereupon, the

תנ

10

20

25

30

(25)

an at least partial fusion between the plastic and the label 2, such as to yield a strong inseparable bond between them. In the embodiment shown in Fig. 3, the label 2 lies somewhat clear of the walls 54 of the mold cavity 44. It is also possible, however, to design the mold 40 such that, for instance, a part of the circumferential edge of the label 2 is locked between the mold parts 42, 46. The label 2 may also be disposed, for instance, at a greater distance from the walls 54 of the mold cavity 44.

The film web 4 is preferably printed, prior to the formation of the labels 2. The film web can, for instance, be rolled up in printed condition to form the roll of film 10 and then be supplied therefrom. In the embodiment shown, for instance, the film web 4 is printed on the side facing the carrier means 6 during cutting. This means that in the mold the heated plastic is sprayed against the unprinted side of the label 2. It is also possible, however, to print the opposite side, while, further, both sides of the labels 2 can be made of printed design.

Fig. 4 shows in top plan view a film web 4 having therein a label 2, cut loose along the contour 26. In broken lines, the outer circumference of the retaining means 14 is drawn on the film web 4. As described above, it can be understood that the contour 26 corresponds to the cutting edge 36 of the cutting means 28. Shown in leading position, viewed in the direction of transport, is the residual material 56 of the film web 4 after the label 2 has been removed therefrom. In Fig. 4 a capital T is drawn by way of printing. It will be clear that any form of printing is possible here.

An apparatus and method according to the present invention provide in particular the advantage that very thin films can be used for forming labels. Thus, labels can be cut from film webs having, for instance, a thickness of 30, 20 or 15 micrometers. Even labels of a thickness of 10 micrometers or less can be cut. In fact, by means of the retaining means 14, in particular the pickup means 18, the film web 4 is kept taut when the labels 2 are being cut loose or blanked, so that damage to the labels is simply prevented. Thin labels have as an advantage that they require little material, that little waste is produced, that they occupy only little volume and have little influence on the end product, while yet a good printing and design are obtained. Moreover, such film webs allow of easy storage and transport.

5

25

30

35

thereby carried along by the engaging parts 64 out of the cavity 44, such that the product 74 too extends, preferably completely, above the closing face 48. As appears from the foregoing, the product 74 is brought in a controlled manner from the position shown in Fig. 6 to the position shown in Fig. 7, retained by the engaging parts, so that the desired position can be readily maintained. The engaging parts 64 and the bounding parts 60 adjoin the side of the product 74 in a form-closing manner and can optionally be slightly pressed against it.

Thereafter, a removal device 76 is moved between the first part 42 and the second part 46 of the mold 40, as shown in Fig. 8, to a point beyond at least one of the bounding parts 60. The removal device 76 is provided, on the side facing the product 74, with first vacuum means 78, controllable through a first vacuum pump 80. The product 74 and/or the first vacuum means 78 are thereby controlled such that the vacuum means 78 contact the surface of the product 74 facing the vacuum means 78 and are activated, such that the product 74 is engaged by the first vacuum means 78.

Thereafter the ejection means 62, at least the bounding parts 60 on opposite sides of the product 74, are moved apart over the distance F, such that the ejection rods 68 come to lie against the outer parts 42A of the first part 42 and the engaging parts 64 are moved out of the product 74. Undercuts 82 in the product 74 as formed by the engaging parts 64 are thereby cleared.

Since the product 74 is retained by the first vacuum means 76, it will not fall back into the cavity 44. The bounding parts 60 are subsequently moved back slightly in the direction T2, for instance to a point close to the closing face 48, such that the product 74 can be pulled away by means of the removal device 76 in the direction K over the adjacent bounding part 60 from between the first part 42 and the closing part 46. Thereafter, the bounding parts 60 can be moved over the distance F again in the direction of the opposite bounding part, so that the ejection means 62 can be returned to the position as shown in Fig. 6. The mold 40 can then be closed again and be used for a next injection molding cycle.

In the embodiment shown, the removal device 76 is provided with second vacuum means 18 on the side located opposite the first vacuum means 78, which second vacuum means 18 are controllable by a second vacuum pump 24, with which inserts such as, for instance, labels 2 can be provided against the closing part 46. Upon closure of the mold 40, such an

insert 2 will be brought into the cavity 44 and may then be incorporated into the product. If use is made of such inserts, it is preferred that the plastic can be introduced through an opening therein into the cavity 44, or that the supply channel 56 terminates remote therefrom and extends, for instance, through the first part 42 into the cavity 44. Such an embodiment will be immediately clear to one skilled in the art.

Using the removal device 76, the product 74 can be displaced outside the mold 40 and there be transferred to, for instance, other processing means. It will be clear, incidentally, that when the opening and closing direction T of the mold 40 is located in an approximately horizontal plane, at least a plane including an angle with the vertical, the product 74 can also be moved away from between the mold parts 42, 46 by gravity when it is released by the engaging parts 64 in the position shown in Fig. 8. In this way, too, a non-withdrawable product can be simply manufactured and product damage due to ejection means is prevented, at least camouflaged. Indeed, during manufacture, the engaging parts 64 fall into the undercuts 82 and will consequently not lead to an unpleasant appearance of the product 74. This is particularly advantageous especially when at least partly transparent products are manufactured.

Fig. 9 shows in a sectional side view a portion of an alternative embodiment of a mold 40, at least of ejection means 62, where in the bounding part 60 two engaging parts 64 are provided above each other in spaced relation, with an undercut 84 enclosed between them. In this embodiment too, during use, a product 74 can be retained by the ejection means 62 and be moved in a controlled manner out of the cavity 44, relative to the first part 42, in that at least a portion of the product is enclosed in a form-closed manner in the undercut 84. Again, the product 74 can be released by moving the different bounding parts 60 apart, such that the undercuts 84 of the product 74 are cleared.

Fig. 10 schematically shows, in top plan view, a cavity 44, for instance as shown in Figs. 6-8, with ejection means 62. Shown in solid lines is the cavity 44, suitable for injection molding a product 74. In the lower half, in broken lines, it is schematically represented how a bounding part 60 in top plan view will move relative to the cavity 44, at least relative to an opposite bounding part 60.

The cavity 44 shown in Fig. 10 is suitable for manufacturing a product 74 with two injection molded hinges 86, so-called living hinges. The hinges 86 extend parallel to each other and parallel to the centerline M, throughout the full width of the cavity 44. Two bounding parts 60 substantially U-shaped in top plan view have been placed with the open side opposite each other and form the outer boundary 88 of the cavity 44. Figs. 10A and 10B schematically show two cross sections of the bounding parts 60 with ejection rod 68, Fig. 10B clearly showing the engaging part 64. In this embodiment, the engaging parts 64 are formed by projections of minor height and width, which extend entirely above a supporting surface 90 of the respective bounding part 60. The supporting surface 90, when the mold is closed, is preferably flush with the bottom surface 58 of the cavity 44 and extends under the hinges 86 in a direction at right angles to the longitudinal direction thereof. The product parts 74A, 74B and 74C extending on opposite sides of the hinge lines 86 (and whose reference numerals are indicated in Fig. 10 in the parts of the cavity 44 where the respective product parts will be manufactured) are therefore supported by the supporting surfaces 90. Such a support provides the advantage that during displacement, in particular during ejection of a thus formed product, the possibility of pivoting of the different parts 74A-C about the hinge lines 86, and unintended disengagement of the product from the engaging parts 64, are simply prevented. This is advantageous in particular also when the hinge lines 86, unlike the embodiment shown in Fig. 10, extend at right angles to the centerline M, since in such an embodiment, upon pivoting of any one of the parts 74A-C, the respective part is pulled from the engaging parts 64.

Fig. 11 schematically shows in perspective view a cavity 44 with ejection means 62 which comprise a bounding part 60 of a cross section comparable to that shown in Fig. 9. However, in this embodiment, the ejection rod 68 is as wide as the bounding part 60. A chain-dotted line 58A indicates the line which is at the level of the bottom 58 of the cavity when the ejector means 62 are fully retracted. In that condition, the top surface 92 will be flush with the closing face 48. In the side of the bounding part 60 proximal to the cavity 44, an undercut in the form of a continuous slot 94 is provided, which is open adjacent the side of the bounding part 60. Above and under the slot 94, engaging parts 64 are provided. In this embodiment,

a product can be removed from ejector means 62 provided on opposite sides of the cavity 44 by sliding the product through the slots 94 in the direction Y, at right angles to the ejection direction T.

Fig. 12 shows a portion of a mold according to Fig. 10 in perspective view, clearly showing the engaging parts 64 which extend above the supporting surface 90 flush with the bottom surface 58. Such a mold can be used, for instance, for manufacturing a package for a compact disc as described in international patent publication WO 97/20315. The engaging parts 64 then form slotted openings in the sidewalls of the package, so that comparable projections can be obtained on the inside of the wall, under which, for instance, a booklet or the like, belonging to the compact disc, can be clamped. Such projections in compact disc packages are known per se. In the manufacture of such a package by means of a method according to the invention, the advantage is achieved that no ejection damage is sustained as a result of the form-closing engagement with the aid of the engaging parts.

Fig. 13 schematically shows a portion of an apparatus according to the invention, in an embodiment in which blanking means are used. This figure shows a forming apparatus 1, for forming labels 2 from a film strip or film web 4. The forming apparatus 1 comprises a carrier 6, for instance a flat table over which the film web 4 is guided, for instance as described in Fig. 1. In the carrier 6, a blanking opening 3 is provided, formed by at least a first blanking plate 5 which is screwed onto the carrier 6 with screws 17. This is shown in more detail in Fig. 13A. Thus the first blanking plate 5 is rapidly exchangeable. On the side of the film web 4 remote from the blanking opening 3, a blanking punch 7 movable, for instance, with the aid of hydraulic cylinders 15, is arranged, having a second blanking plate 9, complementary in shape to the first blanking plate 5. The second blanking plate 9 is screwed against the punch 7, in order to be readily exchangeable, as appears more clearly from Fig. 13A. The first 5 and second blanking plate 9 are relatively thin and can be simply ground. The blanking opening 3 has the shape of the label 2 to be formed. It will be clear that by pressing the punch 7 with the second blanking plate 9 through the film web 4 into the blanking opening 3, the label is cut loose from the film web 4 and is moved into the blanking opening 3.

Into the blanking opening 3, a retaining means 14 has been moved by means of a robot arm 11, represented schematically and only in part. The retaining means 14 is generally comparable with a retaining means 14 as shown in, for instance, Fig. 1 and/or a transfer device 76 as shown in Fig. 8.

5 By means of the robot arm 11, the retaining means 14 can be moved from the position shown in Fig. 13 to the position as shown in Fig. 2 or 8 (where the transfer device 76 is shown as such) and vice versa. The label 2, when it has been cut out with the blanking means 3, 5, 7, 9, is moved by the punch 7 against the retaining means 14 and seized by the pickup means 18. It is  
10 then preferred that the pickup means 18 seize the label-forming part before the label 2 is cut loose, thereby still better preventing the label 2 from deforming during displacement to the mold 30. To that end, the retaining means 14 are made of slightly springing design, either in that the vacuum cups 20 are of slightly elastic design (schematically represented in Fig. 13A  
15 through a hatching 20A behind the cups 20), or in that the retaining means 14 are flexibly connected with the arm 11, or a combination of the two. Other flexible solutions are also possible, of course. Due to this flexibility, the forces acting on the retaining means 14 are reduced still further. The punch 7 is, for instance, driven using hydraulic means 15 and performs a  
20 stroke that is relatively small, for instance a few millimeters to a few centimeters, sufficient on the one hand to move the film 4 between the first and second blanking plate 5, 9 and on the other to move the punch 7 through, at least into, the blanking opening 3. The flexibility mentioned therefore needs to be only small.

25 Around the punch 7 a retaining element (not shown) may be provided which can be moved along with the punch against the film web in order to fix the film web onto the carrier immediately prior to and during blanking or cutting of the labels. Thus, deformation of the labels is prevented still better. With an apparatus 1 according to the invention, particularly thin films can be cut or punched, for instance 15–30  $\mu\text{m}$  or less.  
30 The retaining means 14 can naturally be provided again with means for engaging finished products, such as shown in and described with reference to Fig. 8. Of course, with cutting tools or blanking punches of a different kind, in a comparable manner, an apparatus can be formed whereby the  
35 retaining means 14 can be moved into a cutting or blanking opening for picking up the label, without the retaining means being loaded by cutting or

blanking forces. The first and second blanking plate 5, 9 determine substantially the shape of the labels to be formed. Therefore the apparatus can be simply adapted to differently shaped labels, by exchanging the blanking plates.

5           The invention is not limited in any way to the exemplary embodiments presented in the description and the drawings. Many variations thereof are possible within the framework of the invention outlined by the claims.

10           Thus, the retaining means 14 can be arranged for placing the label in the mold cavity, while the plastic is sprayed, for instance, from the opposite side, or is introduced into the mold cavity through the label. The or each mold cavity may be divided over several mold parts. Also, more than one label can be placed. Since use is made of the retaining means, it is also possible in a simple manner to cut irregularly shaped labels, while in them,  
15           for instance, openings may be provided as well. Also, through a suitable choice of the carrier means and correspondingly adapted retaining means, for instance of single- or double-curve design, a label can be cut which is, for instance, of single- or double-curve design, at least is to be placed on such a curved surface in a mold. This affords a particularly great freedom in  
20           design. Incidentally, also in the surface against which the label is to be placed in the mold, vacuum means or like holding means can be provided for holding the label, for instance when irregularities such as cavities or bulges are to be obtained in it. The vacuum cups can be so arranged that upon creating a reduced pressure therein, the label is slightly stretched, so  
25           that wrinkling or the like is prevented still better.

          In the embodiment shown, the cutting means are included in the carrier means. It will be clear, however, that they can also be provided in the retaining means. Further, the retaining means can be shaped such that the cutting means can cooperate with the outer circumference thereof. Also,  
30           the cutting means can be fixedly arranged, with the label being cut loose by pressing the retaining means and the film web against the carrier means. The label 2 is preferably seized with the pickup means immediately prior to its being cut loose, but this can also take place during or directly upon its being cut loose. A mold according to the invention can be of both single and  
35           multiple design. In the embodiment shown, the label is directly transported with the retaining means to the mold and placed therein. It will be clear

that the label can also be transferred intermediately to a different insertion device on which the label is fixed by comparable vacuum means or the like and subsequently placed in the mold.

With a method and apparatus according to the present invention, a variety of products can be formed. Thus, for instance, packages such as plastic boxes, containers, consumer products, vehicle parts, sheet parts and the like, can be provided with labels, at least printings, which printings are fixedly connected with the product in question. A method according to the present invention is generally applicable for labeling injection molded products. The retaining means are preferably so designed that they can also pick up pre-cut labels, for instance from a stack, and introduce them into the mold. Labels of various kinds and thicknesses can be used.

The mold and in particular the ejector means can be designed differently and can then be moved in a variety of ways. It is preferred that guideways are provided, in which the ejector means are guided along a pre-selected path using, for instance, cam elements or like guide elements, so that always the desired, controlled ejection movement is obtained. However, this controlled movement can also be provided for in a different way, variations which will be immediately clear to one skilled in the art. In the drawing, only one cavity is shown, incorporated in one of the parts of the mold. It will be clear, however, that in a comparable manner, molds can be formed in which the cavity is divided over different mold parts, while moreover a mold according to the invention can be designed as a multiple mold. Moreover, also in the mold according to the invention other moving parts, such as slides and the like, can be used. In the exemplary embodiments shown, the closing part of the mold is of flat design, but it will be clear that, for instance for forming box-shaped packages, mentioned earlier, the closing part may also be provided with a profiling. Also, on the bottom of the cavity in the first part the necessary profiling may be provided. Furthermore, the ejector means can also be wholly or partly provided in the closing part. The bounding parts can also be wholly or partly covered at the top by product parts and can also be pulled away in a direction including an angle with the ejection direction which deviates from 90°, for instance for forming inclined openings.

These and many variations are understood to fall within the scope of the invention outlined by the claims.

ART 34 ANDT

new page 21

## AMENDED CLAIMS

1. A method for manufacturing labels for placement in a mold, in particular in an injection mold, wherein a strip of film is supplied and is placed, by at least a part of a first side thereof, on a supporting carrier, wherein part of said strip, to be referred to as label, is cut out, characterized in that a retaining element is applied to, in particular slightly pressed upon, the second side, remote from the carrier, of the part of the film web supported by the carrier, wherein part of the film web enclosed between the carrier and the retaining element is cut loose, and wherein the enclosed part cut loose, to be referred to as label, is taken hold of by the retaining element and is picked up from the carrier therewith.
2. A method according to claim 1, wherein a retaining element is used which has an outer contour substantially corresponding to that of the desired label, and the label-forming part is cut loose along the outer contour.
3. A method according to claim 1 or 2, wherein the enclosed, label-forming part is taken hold of using vacuum means provided in, at least on, the retaining element.
4. A method according to claim 3, wherein the label-forming part is taken hold of using at least vacuum means extending along the outer contour of the retaining element, such that the label-forming part is pulled taut, at least kept taut, over the retaining element.
5. A method according to any one of the preceding claims, wherein the label-forming part is taken hold of using static charge of the retaining element and/or the label-forming part.
6. A method according to any one of the preceding claims, wherein the label-forming part is taken hold of using adhesion between the label-forming part and the retaining element.
7. A method according to any one of the preceding claims, wherein the label-forming part is taken hold of prior to its being cut loose.
8. A method according to claim 7, wherein the label-forming part, prior to being cut loose, is taken hold of by the carrier.
9. A method according to claim 7 or 8, wherein the label-forming part, prior to being cut loose, is taken hold of by the retaining element.

ART 34 AMDT

new page 22

10. A method according to any one of the preceding claims, wherein the label is transferred from the retaining element to an insertion device for placement of the label in a mold, with the label being taken over by the insertion device in approximately the same position.

11. A method for manufacturing labels for placement in a mold, in particular an injection mold, wherein a strip of film is supplied and is placed, with at least a part of a first side thereof, on a supporting carrier, thereby overlying a blanking opening, characterized in that a retaining element adjacent the strip is brought into, at least adjacent to, the blanking opening; wherein said part overlying the blanking opening, to be referred to as label, is cut out by a blanking punch against the retaining element and is thereby taken hold of and is picked up for transfer to a mold.

12. A method according to claim 11, wherein during blanking the blanking forces are substantially taken up by the carrier, such that the retaining element is substantially not loaded.

13. A method according to claim 11 or 12, wherein on the carrier a first blanking plate surrounding or forming the blanking opening is secured, while on the blanking punch a complementary second blanking plate is secured.

14. A method according to any one of the preceding claims, wherein the film web is printed, prior to the formation of the labels.

15. A method according to claim 14, wherein the printing is provided on the second side of the film web.

16. A method according to any one of the preceding claims, wherein the label, at least the label-forming part, is slightly stretched, at least on the retaining element, preferably during or immediately prior to the label-forming part being taken hold of by the retaining element.

17. A method for placing a label in a mold for in-mold labeling injection molded products, wherein the or each label to be placed is manufactured with a method according to any one of the preceding claims and subsequently is arranged in the mold against at least one wall portion and is secured against it, preferably through reduced pressure, adhesion or static charge.

18. A method according to any one of the preceding claims, wherein labels are manufactured from a film web having a thickness of less than 30

ART 34 AMDT

new page 23

micrometers, more particularly less than 20 micrometers, and preferably less than 15 micrometers.

19. A method according to claim 18, wherein labels are manufactured from a film web of a thickness of less than 10 micrometers.

20. A method for injection molding, wherein in a cavity in a mold a product is injection molded; wherein at least a portion of the cavity is determined by a bounding part which is arranged for movement in an ejection direction, the or each respective bounding part comprising at least one engaging part which is so arranged that, viewed in ejection direction, on both sides of the respective engaging part, a portion of the product, at least of the product space in the cavity is locked, comprising the following steps:  
(a) filling the cavity;  
(b) opening the mold by moving away a closing part;  
(c) moving said movable bounding parts in the ejection direction, while the formed product is held between, at least by, the engaging parts and is moved at least partly out of the cavity;  
(d) moving the engaging parts, such that the product is rendered clear thereof.

21. A method according to claim 20, wherein during or after step (c) the product is engaged with a removal device, prior to or at the beginning of step (d), and the product after step (d) is moved away from the mold in a controlled manner.

22. A method according to claim 21, wherein, using the removal device, the product after step (d) is first moved slightly further into the ejection direction and is subsequently carried away in a direction approximately at right angles to the ejection direction.

23. A method according to any one of claims 21 or 22, wherein using the removal device at least one insert is placed in, at least on the closing part of the mold, preferably approximately simultaneously with the engagement of the product.

24. A method according to any one of claims 20-23, wherein the or each product in the respective cavity is engaged with the engaging means in openings, at least cavities in a longitudinal wall of the product, the or each said movable bounding part further comprising means which engage on the side of the product located rearwards in the ejection direction, for obtaining an improved pressure distribution.

ART 34 AMDT

new page 24

25. A method according to any one of claims 20-24, wherein the product is injection molded with at least one hinge, while on opposite sides of the at least one hinge at least one and preferably at least two engaging means are provided.

26. A method according to claim 25, wherein at least one of said bounding parts extends along the at least one hinge on the side located rearwards in ejection direction, such that the product parts extending on opposite sides of the respective hinge are supported by the respective bounding part, at least during a part of the ejection of the product.

27. An apparatus for manufacturing labels for placement in a mold, in particular an injection mold, comprising:

- supply means for a film web;
- carrier means on which the film web can at least partly be supported;
- cutting means for cutting loose, at least blanking out a label-forming part of the film web;
- characterized in that retaining means are provided which comprise pickup means for holding said label-forming part of the film web, to be referred to as label, such that the label, substantially without deformation, can be picked up with the aid of at least the retaining means, loosely from the further film web, wherein the retaining means are arranged for locking at least the label-forming part against the carrier.

28. An apparatus according to claim 27, wherein the cutting means are arranged for cutting loose, at least blanking the or each label against the retaining means.

29. An apparatus according to claim 27, wherein the carrier means comprise at least one blanking opening, during use covered by the film web, while the retaining means, at least the pickup means, are arranged for movement into the blanking opening, while a blanking punch is provided for blanking in the blanking opening a label from the film web and moving said blanked-out label against the retaining means.

30. An apparatus according to any one of claims 26-29, wherein the blanking opening is formed, at least surrounded, by a first blanking plate, while the blanking punch is provided with a second, complementary blanking plate, the blanking plates being exchangeable with other first and/or second blanking plates.

ART 34 AMDT

new page 25

31. An apparatus according to claim 30, wherein the first and/or the second blanking plate is or are secured with the aid of detachable clamping means.

32. An apparatus according to any one of claims 26-31, wherein the carrier is arranged for taking up substantially the complete blanking forces.

33. An apparatus according to any one of claims 26-32, wherein the pickup means comprise vacuum means at least adjacent a circumferential edge of a surface of the retaining means which during use is moved against the film web, preferably distributed over substantially the entire said surface.

34. An apparatus according to any one of claims 26 or 33, wherein the retaining means comprise a surface which is held against the label during use, and the label is slightly stretched over said surface during use, while the cutting means are arranged for cutting loose the label along the outer contour of said surface.

35. An apparatus according to any one of claims 26-34, wherein the cutting means comprise a blanking punch or cutting tool.

36. An apparatus according to any one of claims 26-35, wherein the retaining means are arranged for directly placing the or each label in a mold.

37. An apparatus according to any one of claims 26-36, wherein an insertion device is provided, arranged for taking over from the retaining means a label picked up therewith, such that it can be transferred with the aid of the insertion device into an opened mold.

38. An apparatus according to any one of claims 26-38, wherein at least the insertion device is provided with a surface for taking over the label, which surface is of a smooth finish, while holding means are provided for taking hold of and holding the label in a slightly stretched condition, which holding means are so designed that they fix the label at some distance from said surface, while in a condition wherein no label is being held they are disposed substantially flush with said surface.

39. A mold, in particular an injection mold, comprising at least one cavity; wherein at least one part bounding the respective cavity engages by at least one engaging part in a product manufactured in the cavity and, with the mold opened, is at least partly movable with the product in the direction of the open side of the respective cavity, in an ejection direction,

ART 34 AMDT

new page 26

while during said movement the respective product is retainable on, at least with, the respective bounding part, and can be transferred to a removal device, at least can be released outside the cavity.

40. A mold according to claim 39, wherein the or each engaging part is provided for engagement of the product in a direction which includes an angle with the ejection direction, in particular an angle of approximately 90° at the beginning of the ejection movement.

41. A mold according to claim 39 or 40, wherein the or each engaging part is arranged for engagement of or behind an undercut in the product.

42. A mold according to any one of claims 39-41, wherein the or each respective bounding part is mounted in guide means which upon movement in the ejection direction take care of the release of the product from the engaging parts near the end of the movement.

43. An injection molded product provided with a printing applied through in-mold labeling, wherein the in-mold label has a thickness of less than 30 micrometers, in particular less than 20 micrometers, more particularly less than 15 micrometers and preferably less than 10 micrometers.

44. An injection molded product, in particular according to claim 43, wherein the product is at least largely transparent and has been demolded from a mold according to any one of claims 39-42.

(54) Title: METHOD AND APPARATUS FOR MANUFACTURING PRODUCTS AND PLACING LABELS IN A MOLD

(57) Abstract: A method for manufacturing labels (2) for placement in a mold, in particular in an injection mold, wherein a strip of film (4) is supplied and is placed, by at least a part of a first side thereof, on a supporting carrier (6), whereafter a retaining element (14) is applied to, in particular slightly pressed upon, the second side, remote from the carrier (6), of the part of the film web (4) supported by the carrier (6), wherein the part of the film web (4) enclosed between the carrier (6) and the retaining element (14) is cut loose, and wherein the enclosed part, to be referred to as label (2), is taken hold of by the retaining element (14) and is picked up from the carrier (6) therewith.

### Declaration and Power of Attorney Patent Application (Design or Utility)

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name,

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled: "Method and apparatus for manufacturing products and placing labels in a mold."

the specification of which

- ☐ is attached hereto  
☒ was filed on February 19, 2002, as application serial no. 10/069,026 and or PCT International Application number PCT/NL00/00581 and was amended on (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information know to me to be material to patentability as defined in 37 C.F.R. §1.56.

I hereby claim foreign priority benefits under 35 U.S.C. §119(a)-(d) or 35 U.S.C. §365(b) of any foreign application(s) for patent or inventor's certificate, or 35 U.S.C. §365(a) of any PCT International application which designated at least one country other than the United States, listed below and have also identified below any foreign application for patent or inventor's certificate of PCT International application having a filing date before that of the application on which priority is claimed.

Prior Foreign Application(s)		
Number 1012869	Country NL	Day/Month/Year Filed 20 August 1999
Number 1012870	Country NL	Day/Month/Year Filed 20 August 1999
Number	Country	Day/Month/Year Filed

10069026 .061302

I hereby claim the benefit under 35 U.S.C. §119(e) of any United States provisional application(s) listed below:

Prior Provisional Application(s)	
Serial Number	Day/Month/Year Filing Date
Serial Number	Day/Month/Year Filing Date
Serial Number	Day/Month/Year Filing Date

I hereby claim the benefit under 35 U.S.C. §120 of any United States application(s), or under 35 U.S.C. §365(c) of any PCT International application designating the United States, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States or PCT International application in the manner provided by the first paragraph of 35 U.S.C. §112, I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in 37 C.F.R. §1.56 which became available between the filing date of the prior application and the national or PCT International filing date of this application:

Prior U.S. or International Application(s)		
Serial Number	Day/Month/Year Filed	Status (patented, pending, abandoned)
Serial Number	Day/Month/Year Filed	Status (patented, pending, abandoned)
Serial Number	Day/Month/Year Filed	Status (patented, pending, abandoned)

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements are made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under 18 U.S.C. §1001 and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

10069026 .061302

## Power of Attorney

As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.
